# Introduction

- In this project, a song recommendation system has been implemented, experimented, and designed.
- This recommendation system builds up a users profile based on his/her past records, and compares it with some reference characteristics.
- Then, it seeks to predict songs that a user would not have listened before.

# Introduction(contd)

- One of the most promising technologies is collaborative filtering.
- Collaborative filtering works by building a database of preferences for items by users.
- Methods used for collaborative filtering :
  - User-user Collaborative Filtering
  - Item-item Collaborative Filtering
- In this project, item-item collaborative filtering has been implemented.

# The User-Song Matrix

**User-Song Matrix [1M x 200]**

USERS/SONGS	SONG-1	SONG-2	SONG-3	,	,	SONG-200
USER-1						
USER-2						
USER-3						
,						
,						
,						
,						
USER-1M						

Figure: The User-Song Matrix

# Similarity Functions

- **Weighted Average:** This approach computes the prediction on an item  $i$  for a user  $u$  by computing the sum of the play counts given by the user on similar items to  $i$ . Each play count is weighted by the corresponding similarity  $s_{i,j}$  between items  $i$  and  $j$ .

$$P_{u,i} = \frac{\sum_{\text{all similar items, } N} (S_{i,N} * R_{u,N})}{\sum_{\text{all similar items, } N} (|S_{i,N}|)}$$

# Similarity Functions (contd)

- Cosine-based Similarity: Two items are considered as two vectors in a dimensional space. The similarity between them is measured by computing the cosine of the angle between these two vectors.

$$sim(i,j) = \frac{\sum_{u \in U} (R_{u,i})(R_{u,j})}{\sqrt{\sum_{u \in U} (R_{u,i})^2} \sqrt{\sum_{u \in U} (R_{u,j})^2}}$$

- Adjusted Cosine Similarity: Here, corresponding user average is subtracted from each co-rated pair.

$$sim(i,j) = \frac{\sum_{u \in U} (R_{u,i} - \vec{R}_u)(R_{u,j} - \vec{R}_u)}{\sqrt{\sum_{u \in U} (R_{u,i} - \vec{R}_u)^2} \sqrt{\sum_{u \in U} (R_{u,j} - \vec{R}_u)^2}}$$

# Mean Absolute Error

- Measure of deviation of recommendations from their true user specified values
- Given formula:

$$\mathbf{MAE} = \frac{\sum_{i=1}^N |p_i - q_i|}{N}$$

- where
  - $p_i$  : Obtained Value
  - $q_i$  : Predicted Value
  - $N$  : Total Number of Songs

# Initial Approach

In this matrix- rows signify users and columns signify songs.

- Each element  $U \times S$  of the matrix is the play count for the song  $S$  by user  $U$ .
- So each row is analogous to a user with the values in the row signifying the play count for songs where song numbers correspond to column numbers.
- A single column [**1M users x 1 song**] will be referred to as a song and each row [**1 user x 200 songs**] will be referred to as a user.

# Initial Approach (contd)

- Application of cosine similarity algorithm to find the 10 most similar songs for each of the 20 test songs and took a weighted average of the 10 most similar songs for each of the 20 test songs and compute a predicted version of the test dataset matrix.

```
In [84]: mean_absolute_error(test_data, np rint(predicted_data))  
Out[84]: 0.097200299999999989
```

Figure: 1st MAE Result

# Normalization L1 Norm

- In this attempt, the values of the play counts are normalized for each user before splitting the matrix and applying the rest of the cosine similarity and weighted average procedure.
- Normalizing the matrix improves results because play counts of a song do not have rigid boundaries and different users may have different average play count numbers.
- In order to address the above issue, we decided to normalize the dataset between 0 and 1.

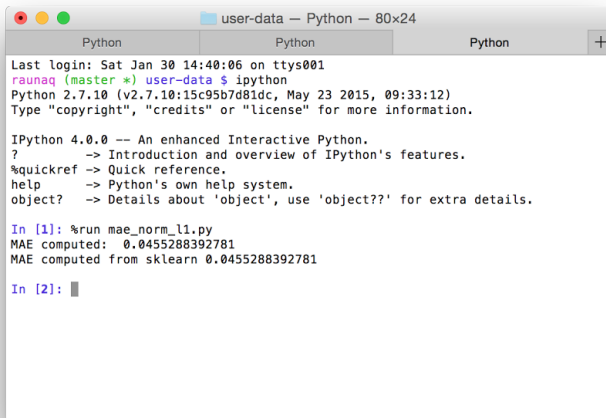

# Normalization L1 Norm (contd)

- In this attempt the normalization formula, each play count is normalized between 0 and 1:

$$\text{L1 Norm} = \frac{\text{User's Play Count for Particular Song}}{\text{User's Cumulative Play Count}}$$

# Normalization L1 Norm (contd)

- On using this formula, each play count is between 0 and 1 such that the cumulative play count will be 1.

# Normalization Min-Max Formula

- On using this formula, every play count lies between 0 and 1 but the sum of the row is not necessarily 1.
- For the sake of convenience, this formula is referred to as min-max normalization.

$$\text{Min-Max Norm} = \frac{\text{Play Count} - \text{Minimum Play Count}}{\text{Maximum Play Count} - \text{Minimum Play Count}}$$

# Normalization Min-Max Formula (contd)

# Normalization Train and Test

- The matrix is split before it is normalized and then normalize the training matrix (1M users  $\times$  180 songs) and the test matrix (1M users  $\times$  20 songs) separately.
- The min-max normalization formula is used for normalizing .

# Normalization Train and Test (contd)

The best MAE is obtained

Figure: 4th MAE Result

# Conclusion

This presentation is concluded as follows:

- MAE has reduced gradually step by step.
- Further on, adjusted cosine similarity will be implemented.
